

# **TEN 5-2411**

6W, 1500VDC isolated voltage regulator single/positive/negative output DC-DC module power supply

- Ultra-wide input voltage range: 4:1
- Low standby power consumption: 0.15W(typ)
- Low ripple noise 75mV(typ)
- Input undervoltage protection
- Output short-circuit protection (self-recovery)
- Operating temperature: -40℃ ~+85℃

This series of module power supply is suitable for the power supply circuit where the input voltage changes greatly and the input and output must be isolated. Its ultra-wide input voltage range (4:1), high stability of the output voltage, low ripple noise, efficient and reliable characteristics, especially suitable for industrial control system power supply, communication system power supply, power monitoring system power supply, instrumentation power supply and other power systems.

Selection list						
Model number	Nominal value of input voltage	Input voltage range	Output nominal voltage	Output rated current	Full-load efficiency (%_typ)	Maximum capacitive load <sub>(</sub> µF <sub>)</sub>
			3.3V	1500mA	78	3300

### **DC-DC module power supply**

#### Product Characteristic Curve 1 (Temperature derating and conversion efficiency)

#### Precautions for use

1. Consideration of additional input capacitance:

There are a variety of interference noises in the input line of the power supply. The frequency is high, the duration is short, but the peak value is very high. In order to make the power supply work stably and reliably, it is usually necessary to add a suitable absorption capacitance at the input end. In some cases, the lead between the power supply and the power supply on the PCBA board is very long, then it is necessary to connect the filter capacitor near the input pin of the power supply to achieve the effect of impedance matching. The greater the interference noise, the longer the line, the greater the required external capacitance value. We recommend the use of high frequency and low resistance electrolytic capacitors, general application, can be selected according to the recommended value of the "Design reference chapter".

2, the consideration of the output filter capacitance:

In the actual application circuit, the load size of the power supply varies, usually accompanied by large or small changes. In order to adapt it to different use occasions and load requirements, and work more stably and reliably, it is necessary to add a suitable capacitor to the output end of the power supply. On the one hand, to further reduce the output ripple and noise; On the other hand, the output voltage amplitude fluctuation caused by load jump is reduced by applying output capacitance to make the output voltage more stable. However, the output end can not add too large capacity capacitance, the larger the output capacitance, the power supply needs to start the instantaneous current provided by the power supply end will increase, and may even cause its output voltage can not be established; In addition, the capacitance value at the output end is too large, and the power supply is prone to output overshoot when starting. Therefore, in order to make the power supply work more stably and reliably, the output capacitance should be reduced as much as possible when the output voltage fluctuation amplitude caused by the load jump meets the requirements. The maximum capacitive load in the selection list only means that the power supply can start normally when the total capacitance of its output is within this value, and we do not recommend it. We recommend the use of high frequency and low resistance electrolytic capacitors, recommended values please see the "Design reference chapter".

3. Prevent hot swap test or use of the power module:

When the power supply is not disconnected, inserting the power supply into or removing it from the circuit is a hot swap operation. The power supply does not support hot swap during use or testing. Because in the hot swap process, due to the current mutation will produce high voltage spike, it may cause damage; In another case, a mechanical switch is connected in series between the power supply and the input end of the power supply product, and the power supply is controlled on and off by the mechanical switch. The mechanical switch will also produce high voltage spikes during on-off operation, which may also cause damage to the power supply. Power supply products in the test or use process, any operation that will produce high voltage spikes should not be ignored, need to take measures to prevent high voltage spikes directly added to its input, refer to the "Design reference chapter".

4, input high transient voltage peak protection:

If the product is used in an environment with harsh electromagnetic interference, for example, the input end of the product shares the power supply with the inductive load, or the power supply end When the current loop is on/off, if not handled properly, there will be a high transient voltage spike in the power supply circuit, this interference is not dealt with, and too high peak voltage enters the product input, which is likely to cause product damage. The suppression of high voltage spikes is very important to ensure the stable and reliable use of the product. Commonly used transient voltage suppression devices are varistor (MOV), transient voltage suppression diode (TVS) and so on. Different devices have advantages and disadvantages, please choose according to the use of the occasion and requirements, refer to the "Design reference chapter".

5, positive and negative output load balance requirements:

The actual load of the positive and negative output products usually has an imbalance between the two loads. In this case, the voltage of the negative output will change with the change of the load of the two channels. When the main load is constant, the negative output voltage will increase with the decrease of the load. When the negative output load is constant, the negative output voltage decreases with the decrease of the positive output load and increases with the increase of the positive output load and increases with the increase of the positive output load and increases with the increase of the positive output load and increases with the increase of the positive output load and increases with the increase of the positive output load and increases with the increase of the positive output load is much smaller than the negative output load, it will even cause the product to not work properly. In practical applications, it is necessary to fully consider whether the extreme situation of the two-way load meets the requirements, and improve the balance of the two-way load and provide the positive output is provided and provided in the positive output load is much smaller than the positive of the two-way load meets the requirements.

as much as possible to make the product work more stable and reliable.

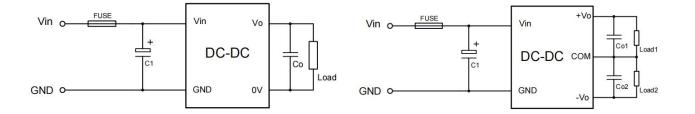

6, input polarity and output power expansion:

The inputend of the product has no anti-reverse protection, please note: the input polarity willcause damage to the product when in use. To achieve anti-reverse or non-polar use without damaging the product, a diode or rectifier bridge can be connected in series at the input end, refer to the "Design Reference section"; In addition, the product does not support output parallel to achieve output power expansion, please choose our higher power level products.

		15V	220uF/25V	±24V	±47uF/50V

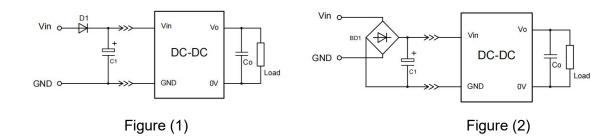

#### External capacitance values (Table 1)

Note: The input and output capacitors are recommended to use high-frequency and low-resistance electrolytic capacitors, whose capacity values can be referred to (Table 1), and the output capacitors can also use MLCC capacitors. The external capacitance should be as close as possible to the input and output pins of the product; In addition to the use of high-frequency electrolytic capacitors, a 0.1uF chip capacitor is added.

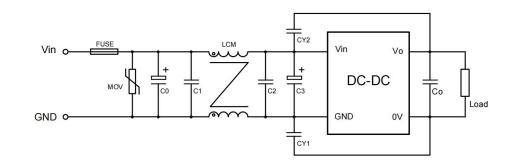

The input anti-reverse connection function can be realized by using the circuit in Figure (1). The non-polar input can be used by using the circuit in Figure (2). Among them, diode D1 is recommended to use a

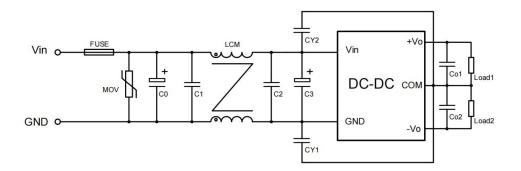

Schottky diode with a small on-voltage drop, and rectifier bridge BD1 is recommended to use a low-voltage drop rectifier bridge. If the conduction pressure drop is large, the loss is large and the heat is serious during use. The rated voltage and current of diode D1 and rectifier bridge BD1 should have sufficient margin, and the current must meet the temperature derating requirements.

3、EMC Recommended circuit:

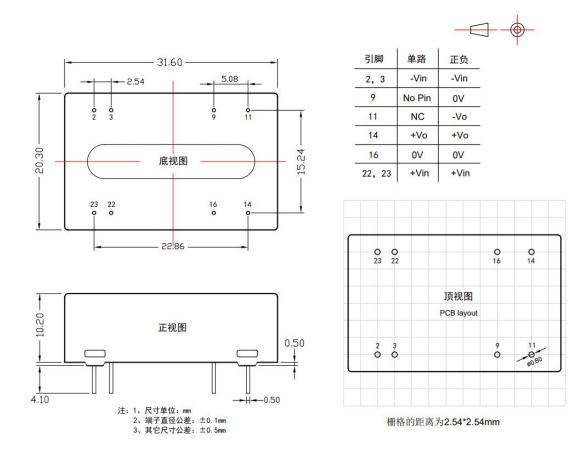

Component parameter description :						
Component code	PA(B)24xxMP-6WN	PA(B)48xxMP-6WN				
FUSE	Select according to the actual current size					
MOV	20D470K 14D101K					
C0 C3	470uF/50V	220uF/100V				
C1 C2	4.7uF/50V 4.7uF/100V					
LCM	10mH	10mH				
CY1 CY2	2.2nF/2KV	2.2nF/2KV				
Co Co1 Co2	Select according to (Table 1)					

#### Appearance size and pin function

#### Note:

1. For specific packaging information, please refer to the "Product Shipping Packaging Instructions";

2. If the working load of the product is lower than the minimum load requirements, we cannot guarantee that the product performance can meet all performance indicators;

3. The maximum capacitive load is tested in the input voltage range and under full load conditions;

4. Unless otherwise specified, all indicators in this manual are measured at Ta=25°C, humidity <75%RH, nominal input voltage and rated output load;

5. All index test methods in this manual are based on the company's enterprise standards;

6. Our company can provide product customization, specific circumstances can directly contact our technical personnel;

7. Products related to laws and regulations: see "Product Characteristics", "EMC characteristics";

8. Our products shall be classified and stored in accordance with ISO14001 and relevant environmental laws and regulations after scrapping, and handed over to qualified units.
